Format: Header: The header (in ASCII) encodes the number of bytes for the header followed by the number of data points in bytes for the raw data. ASCII #42000 Header identifier Indicates the number of characters that will encode the number of data points (ie. 2000 = 4 characters) after which the raw data will follow. Indicates the number of bytes that follow (for the raw data). Raw Data: Each two bytes (in hex) encodes the vertical data of a data point. The data is signed hex data (2's complement, -32768 ~ 32767). Waveform Raw Data Example: Header raw data……. Hex: 23 34 32 30 30 30 00 1C 00 1B 00 1A 00 1A 00 1B

	…….. ASCII/Decimal: #42000 28 27 26 26 27……. The actual value of a data point can be calculated with the following formula: (Decimal value of hex data/AD Factor) * vertical scale. Note: AD Factor is fixed as 25. The vertical scale is returned with the acquisition settings that precede the raw data. For example if the raw data for a point is 001C (=28 decimal) then, (28/25) x 0.5 = 0.56V
